List of figures:

- Figure S1.** Homology-based dendrogram of VSG proteins.
- Figure S2.** Differences between the two chromosomal homologues at the left hand of chromosome 8.
- Figure S3.** Phylogenetic reconstruction of the ARF subfamily of small GTPases.
- Figure S4.** Phylogenetic evidence for horizontal transfer of genes for haem biosynthesis in *Leishmania major*.
- Figure S5.** Phylogenetic evidence for horizontal transfer of 2-aminoethylphosphonate:pyruvateaminotransferase

List of tables:

- Table S1.** Sequence status of the *Trypanosoma brucei* megabase chromosomes.
- Table S2.** *Trypanosoma brucei* protein-coding families.
- Table S3.** Catalogue of genes coding for variant surface glycoproteins (VSGs).
- Table S4.** Catalogue of expression site associated genes (ESAGs).
- Table S5.** Complete list of proteins discussed in the trafficking section.
- Table S6.** Coatomer and adaptin family representation in the Kinetoplastida, metazoans and fungi.
- Table S7.** Rab family GTPase representation in Kinetoplastida, Apicomplexa, fungi and metazoans.
- Table S8.** Complete list of proteins discussed in the cytoskeleton section.
- Table S9.** Tritryp transporters.
- Table S10.** List of enzymes identified in the Tritryp genomes.
- Table S11.** List of strongest phylogenetic tree-based cases for prokaryote to eukaryote horizontal gene transfer in the Tritryps.

Materials and Methods

Sequencing

The methodology for preparation of *Trypanosoma brucei* strain TREU (Trypanosomiasis Research Edinburgh University) 927/4 (GPAL/KE/70/EATRO 1534) single VAT derivative GUTat 10.1 stocks, DNA library construction and sequencing have been described elsewhere (1, 2). The two sequencing centres employed different sequencing strategies. Chromosome 1 and 9-11 were sequenced at the WTSI, using a whole chromosome shotgun approach (1). For the latter, chromosomal homologues were assembled into haploid consensus sequences annotated with polymorphisms where found. However, in Tb, homologous chromosome pairs are known to vary in size (3) and individual homologues of chromosome 1 and 9 could be partially separated and isolated from pulsed-field gels, increasing the proportion of DNA of that homologue in the shotgun-sequencing library. Chromosomes 2-8 were sequenced at TIGR using a BAC walking approach (2), whereby overlapping 85-170 kb BAC clones were mapped to individual chromosomes and ‘shotgun’ sequenced. Consequently, the sequences of chromosomes 2-8 also represent a ‘mosaic’ assembly of both chromosomal homologues. Due to under-representation in the BAC library, not all telomeres were sequenced. In one instance however (left hand end of chromosome 8), the sequence of two BACs representing the two homologues could be assembled separately. Optical (D Schwartz, unpublished) and genetic (4) maps were used to order and orientate contiguous sequences (contigs) during gap closure.

The sequence analysis published here constitutes release 4 of the *T. brucei* genome accessible via the curated genome database GeneDB (<http://www.genedb.org>) and the following FTP sites: ftp://ftp.tigr.org/pub/data/Eukaryotic_Projects/t_brucei and ftp://ftp.sanger.ac.uk/pub/databases/T.brucei_sequences. Chromosomes 1 – 10 were assembled into

single pseudomolecules while chromosome 11 is presented as 3 scaffolds of known order (Table S1). Where appropriate, the gaps between consecutive contigs within scaffolds are represented as strings of 100 letter Ns in the sequence. With some exceptions, the assembled pseudomolecules end in the subtelomeric region (Table S1). As the optical maps generated for each chromosome represent a mixture of both homologues, comparisons between the subtelomeric sequences with the respective optical maps provided little indication as to the distance from the telomeric hexamer repeat due to variations between homologues in this region.

Annotation

Putative protein coding regions (>30 codons) were predicted by combining the output of the gene finding algorithm Glimmer (5) with similarity data and manual annotation of open reading frames as described previously (1, 2). This annotation included the assignment of Gene Ontology (GO) terms (6). Further refinement of gene models (additions, deletions and alterations to boundary coordinates) were done manually based on detailed comparisons with the *T. cruzi* and *L. major* genomes (see Tritryp comparative paper). Genes on finished chromosomes were assigned systematic identifiers according to the scheme described previously (2). Genes on chr3-8 were also assigned a secondary systematic name based on the chromosome and the BAC from which they originated (e.g. Tb03.27F10.410). Genes on unfinished chromosomes were given temporary identifiers. The analysis presented here does not include short predicted coding sequences (less than 150 codons) with no additional evidence of coding potential, these ‘unlikely coding sequences’ are included in the available annotation with the following product line ‘hypothetical protein, unlikely’.

To limit annotation discrepancies between the two centres, common standards for the annotation were defined. Gene products were assigned a putative function when they shared significant similarity with experimentally characterised gene products or when they contained functionally known protein domains. Remaining gene products were labelled either “hypothetical protein”, or

“hypothetical protein, conserved” in the case of products showing significant similarity with proteins or domains of unknown function from other organisms. In addition, the same 100 kb contig from chromosome 10 was annotated at WTSI and TIGR to standardise annotation criteria.

To enable both centres to annotate as well as analyse the whole *T. brucei* genome, sequence data and annotation were regularly exchanged. Both in-house databases, TGAD (<http://www.tigr.org/tdb/e2k1/tba1/tba1.shtml>) at TIGR and GeneDB (<http://www.genedb.org>) at WTSI, were synchronised by transferring and comparing data in an XML format (<ftp://ftp.tigr.org/pub/data/DTDs/tigrxml.dtd>). Comparisons included changes to gene attributes, such as gene product names, as well as the addition and deletion of genes, and changes to coordinates. Annotation updates committed by one centre as well as conflicting annotations were identified using custom Perl scripts and a purpose-written MySQL relational database. Updates at both TIGR and WTSI were performed automatically with conflicts subsequently resolved manually, as a collaborative exercise between both centres.

Protein-coding genes were clustered into gene families using TRIBE-MCL (7) with an inflation value parameter of 4. An E-value of 1e-15 was used as a BLASTP cut-off to generate the families shown in Tables S2.

Analysis

VSG analysis

Putative *VSGs* were identified by similarity searches using the TBLASTX algorithm (8) against the UniProt protein database (9). Putative *VSG* genes were checked for presence of a predicted signal peptide using the SignalP2.0 prediction tool (10) and of a GPI anchor signal sequence by similarity with conserved *VSG* GPI signal sequences (11) as well as using two GPI signal prediction programs, big-PI predictor (12) and DGPI (http://129.194.185.165/dgpi/DGPI_demo_en.html). The domain composition of each putative *VSG* was established by the presence and spacing of cysteine residues

and according to the domain type to which it best aligned to, taking account of gaps where appropriate (11, 13). Where applicable, the boundary between the two N and C terminal domain was set at 50 amino acids upstream of the first conserved cysteine in the C terminal domain.

Putative *VSG* genes/proteins were classified into 4 categories: (1) Putative full-length coding sequences, with signal peptide and GPI signal both predicted to be functional and bearing an intact cysteine pattern. (2) Atypical *VSG* genes, full-length coding sequences that have diverged from the expressed *VSG* consensus sequence (with respect to signal peptide, GPI signal, or cysteine pattern). (3) Pseudogenes, defined as genes with frameshifts, stop codons or incomplete sequences. (4) VSG-related proteins were defined by their inclusion into a distinct cluster in a multiple alignment [using ClustalW (<http://www.ebi.ac.uk/clustalw>)] against characterised VSGs.

76-bp repeat sequences were manually annotated based on the published consensus sequence (14). The ~29-bp-long GC-rich subtelomeric element (15) was mapped similarly, usind a consensus sequence generated from sequences available in public databases using the MEME software (16).

Trafficking & Cytoskeleton

To identify potential components of the cytoskeleton as well as the trafficking pathways, the annotation of the Tritryp genomes was searched in GeneDB using keywords. In addition, the Tritryp genomes were queried (using BLASTP, TBLASTN) (8) against a reference set of proteins from the yeasts (*S. cerevisiae*, *S. pombe*), humans, plants (*A. thaliana*) and other organisms for which a complete or near complete genome sequence (e.g. *P. falciparum*, *C. parvum*, *G. lamblia*, *E. cuniculi*) was available. This was complemented by Pfam searches for domains characteristic of cytoskeletal proteins (<http://www.sanger.ac.uk/Software/Pfam/>). From this starting set, unlikely members (including fragments and predicted proteins lacking essential domains) were removed. Multiple alignments of predicted protein sequence were created using the ClustalX software

(<http://www.ebi.ac.uk/clustalw>) followed by manual adjustment (see Table S6 for the reference set detailing cytoskeletal proteins).

To confirm or refute orthology of proteins involved in trafficking, the sequences of putative Tritryp homologues were in turn searched against the non-redundant database at NCBI (<http://www.ncbi.nlm.nih.gov/BLAST/>) or alternatively, the yeast, human or other selected completed genomes as appropriate. In addition to similarity searches, protein sequences were analysed for the presence of defining domains (presence of the WDTAQ box and a (mostly) C terminal prenylation motifs in the case of Rab proteins, and N-terminal acylation signals in the case of ARFs). Classification of Tritryp Rab proteins were made in comparison to a previously described reference set (17). Phylogenetic analyses of proteins involved in trafficking and the cytoskeleton were carried out using the maximum-parsimony schema PAUP 4.0 (<http://paup.csit.fsu.edu>) using a distance algorithm and Neighbour Joining method and, where appropriate, data were subjected to bootstrapping analyses.

Transporter

The entire Tritryp predicted gene complement (37,332 CDS) were assessed by similarity searches (BLASTP) (8) against transporter components lodged in the TCDB database (<http://tcdb.ucsd.edu/index.php>). All proteins in the TCDB database have been annotated with an International Union of Biochemistry and Molecular Biology number (IUBMB, <http://www.chem.qmul.ac.uk/iubmb/>) approved classification system for membrane transport proteins: the Transporter Classification (TC) system. Tritryp proteins were classified transitively from the respective TCDB protein, and hence TC, exhibiting the highest BLASTP similarity. A maximum E-value cut-off of 1e-05 was applied.

Metabolism

To reconstruct metabolic pathways, each predicted coding sequence was automatically associated with GO terms using the GOTcha program (18). Predicted GO annotations with a P-score in excess of 50% and GO annotations manually curated from the scientific literature were converted to the EC number classification of enzyme-catalysed reactions (International Union of Biochemistry and Molecular Biology, www.chem.qmul.ac.uk/iubmb/enzyme/), using EC number-GO term mapping provided by the Gene Ontology Consortium (www.geneontology.org). This analysis was performed for all three genomes and the EC numbers mapped to metabolic pathway diagrams from the Kyoto Encyclopaedia of Genes and Genomes (www.genome.jp/kegg/). The diagrams were coloured to indicate, for each enzyme, the predicted likelihood of it being present in each organism. This facilitated a rapid assessment of the metabolic pathways, the supporting evidence for each assignment being reached by clicking through the relevant metabolic map to obtain the candidate gene lists and provide hyperlinks to each gene's annotation in GeneDB. Ambiguous hits were reassessed manually by detailed examination of BLASTP similarity search results against the non-redundant protein database at NCBI.

Phylogenetic trees for detecting prokaryote to eukaryote HGT

The trees included as supplementary information are consensus Bayesian trees generated using the following approach.

A crude BLAST based screen was performed to prepare a list of candidates cases of horizontal transfer from prokaryotes. BLASTP 2.0 was used to search each gene against the non-redundant Uniprot database. Genes with a greater top BLAST score to a prokaryotic than to a eukaryote were subjected to a phylogenetic analysis.

For each candidate HGT identified we searched all available databases, including those based upon EST surveys, to maximize sampling - particularly for eukaryotic sequences. Sequences from Blast searches were included in alignments if they showed at least 40% similarity over >70 and <200% of

the length of the query sequence. The recovered sequences were aligned as proteins using ClustalW followed by manual inspection to remove positions of uncertain alignment and gap regions. Each edited alignment was analyzed by MrBayes (19) using the WAG matrix, a gamma correction for site rate variation and a proportion (pinvar) of invariant sites. The analyses were run for 600,000 generations and sampled every 100 generations, with the first 2000 samples (33%) discarded as a conservative burn-in. A consensus tree was made from the remaining samples. Because posterior probabilities, the support values used by Bayesian analysis to indicate confidence in groups, have been criticized (20), we also use bootstrapping to provide an additional indication of support for relationships. Each data set was bootstrapped (100 replicates) and used to make distance matrices under the same evolutionary model as in the Bayesian analysis, using custom (P4) software (p.foster@nhm.ac.uk). Trees were made from the distance matrices using FastME (21) and a bootstrap consensus tree made using P4.

Interpretation of trees and support values

Posterior probabilities and bootstrap support values (PP/BS) are given on the Bayesian consensus trees, an asterisk following a BS value is given when the relationship was not recovered in the distance bootstrap consensus tree but appeared in some bootstrap replicates, no BS value means that the relationship did not appear among the bootstrap replicates.

Figure legends of supplementary information

Fig. S1. Homology-based dendrogram of VSG proteins, colour-coded by the array in which they are localised. Colours are entirely randomly mixed, indicating a lack of conservation between VSGs of the same array

Fig. S2. Differences between the two chromosomal homologues at the left hand of chromosome 8.

The grey bars represent the forward and reverse strands of BAC 27P2 (top) and the left hand end of the assembled chromosome 8 (bottom). The coloured boxes denote annotated gene models. The red lines between the sequences represent 6 frame translated DNA versus 6 frame translated DNA similarities (TBLASTX matches, HSP overlap 150 nt, Score 150, Id 50%) between the two sequences.

Fig. S3. Phylogenetic reconstruction of the ARF subfamily of small GTPases in the Tritryps.

Low sequence conservation between the trypanosome and higher eukaryote ARF family results in poor segregation by local alignment. Hence a large tree consisting of all ARF and ARL family sequences from Tb, Tc and Lm, together with sequences of ARF1-6 and ARL1-8 from mammals was used to identify the ARF and ARL families in the trypanosome genomes (data not shown). These sequences were then used to build a limited tree containing only the ARF family. Note that the mammalian and kinetoplastid sequences fully segregate, indicating that the last common ancestor has a single ARF. Note also the presence of several nodes that contain multiple copies of near or fully identical ORFs (highlighted in red). Phylogenetic reconstruction was performed by alignment of retrieved ARF sequences from GeneDB using ClustalX and default parameters, followed by trimming of sequences with abnormal N or C-terminal extensions. The tree was built with PAUP 4.0* using the distance algorithm and Neighbour Joining routine and was subjected to 1000 bootstraps. *; branches supported by bootstrap values <75%. Overall, the reconstruction is highly robust. Sequences in the phylogenetic analyses were: human ARF1 (P32889), human ARF3 (P16587), human ARF4 (P18085), human ARF5 (P26437), human AFR6 (P26438) and bovine ARF2 (P84081).

Fig. S4. Phylogenetic tree-based evidenced for horizontal transfer of genes for haem biosynthesis in *L. major*.

(a) coproporphyrinogen III oxidase, (b) protoporphyrinogen IX oxidase, (c) ferrochelatase.

Fig. S5. Phylogenetic evidence for horizontal transfer of 2-aminoethylphosphonate:pyruvate aminotransferase

⁵ Chromosome assembled into 3 ordered scaffolds, where scaffold 1 is linked to scaffold 2 by genetic marker and scaffold 2 is in turn linked to scaffold 3 by genetic marker.

⁶ personal communication: Dave Barry, University of Glasgow, UK.

Sequence gaps are defined as gaps spanned by paired reads from either a sequencing clone, originating from a small (2-4kb) insert library, or a BAC clone (insert size 20-25kb or 50-120kb). The gap between consecutive contigs has been arbitrarily set to 100 bases (represented as "n"s in the sequence). In instances where scaffolds are linked by genetic markers (McLeod *et al.* unpublished), this has been defined as physical gaps. Physical gaps have also been included where pseudomolecule sequence assembly does not extend to recognisable telomeric sequences.

The sequence at the ends of the pseudomolecules was analysed for repeats as described in the Materials and Methods. 'Left' refers to the left hand end of the respective chromosome, whilst 'right' refers to the right hand end. Where left blank, pseudomolecule assemblies end in the subtelomeric region but not in recognisable repeats.

^a AP1 and AP2 beta chains are indistinguishable using phylogenetics

^b Tb06.5F5.640 has a probable N-terminal extension:

MQGLIVVTTV SHLFIAISHE REISFSNFFF FIEITGGHLC VTA

^c forms too divergent in Tritryps to be assigned

Colour scheme:

grey	absent in the Tritryps
white	present in Lm, Tb, Tc
red	only present in Lm
purple	only present in Tb
blue	only present in Tc
orange	only present in Lm, Tb
teal	only present in Lm, Tc
yellow	only present in Tb, Tc

Table S6. Coatomer and adaptin family representation in the Kinetoplastida, metazoans and fungi.

Functional assignments based on work in metazoan and yeast systems. Not all of these functions are likely to be represented in the Kinetoplastida.

Note that the adaptins, coatomers and other classes described here, with the exception of COP II, are all considered to have a common evolutionary origin (Boehm and Bonifacino 2001). ‘+’ indicates the presence of at least one copy of a given orthologue in the species, while ‘–’ indicates its absence.

S.c., *Saccharomyces cerevisiae*; *H.s.*, *Homo sapiens*

Complex	Known or proposed function(s)	<i>T.b</i>	<i>T.c</i>	<i>L.m</i>	<i>S.c</i>	<i>H.s</i>
AP-1	Sorting at the <i>trans</i> -Golgi network (TGN)	+	+	+	+	+
AP-2	Endocytic vesicle assembly at the plasma membrane	-	+	+	+	+
AP-3	Sorting from early endosomes to later organelles in secretory pathway	+	+	+	+	+
AP-4	Targeting proteins from the TGN to basolateral plasma membrane	+	+	-	-	+
COP I	Intra-Golgi and post-Golgi transport. Retrograde transport.	+	+	+	+	+
GGA	Targeting proteins from the TGN to the lysosome and other destinations	-	-	-	+	+
Stonin	Endocytosis; interaction with AP-complexes	-	-	-	-	+
COP II	Exit from the ER, ER to Golgi transport.	+	+	+	+	+

Table S7. Rab family GTPase representation in Kinetoplastida, Apicomplexa, fungi and metazoans.

The Rab nomenclature is based on previous reports {Ackers, in press #418}, {Pereira-Leal, 2000 #421}. The functional assignments are based on work in metazoan and yeast systems, as well as direct analysis of members of the *T. brucei* and *L. major* Rab families. ‘+’ indicates the presence of at least one copy of a given orthologue in the species, while ‘-’ indicates its absence. For the Kinetoplastida, the number in parenthesis specifies the number of isoforms. (*P.f.*, *Plasmodium falciparum*; *S.c.*, *Saccharomyces cerevisiae*; *H.s.*, *Homo sapiens*).

Rab	Known or proposed function(s) ¹	<i>T.b</i>	<i>T.c</i>	<i>L.m</i>	<i>P.f</i>	<i>S.c</i>	<i>H.s</i>
1	ER to Golgi transport, intra-Golgi transport	+ (2)	+	+	+	+	+
2	ER to Golgi transport, intra-Golgi transport	+	+	+	+	-	+
4	Rapid recycling and lysosomal targeting	+	+	+	-	-	+
5	Endocytosis	+ (2)	+ (2)	+ (2)	+	+	+
6	Retrograde transport through the Golgi stack	+	+	+	+	-	+
7	Late endosome and lysosomal delivery	+	+	+	+	+	+
11	Recycling of plasma membrane components	+	+	+	+	+	+
18	Golgi localized, probable role in exocytosis	+	+	+	+	-	+
14	Transport from the Golgi to endosomes	-	+	+	-	-	+
21	Not known	+	+	+	-	-	+
23	Endosomal function (metazoans); nuclear function (tryps)	+	+	+	-	-	+
28	Not known – possibly similar to Rab23	+	+	+	-	-	+
32	mitochondrial anchoring of PKA and mitochondrial dynamics, possible role in melanocyte biogenesis.	-	+	-	-	-	+
X1	Not known – ER localised	+	+	+	-	-	-
X2	Not known – Golgi localised	+	+	+	-	-	-
X3	Not known	+	+	+	-	-	-

Supplementary Table S8.
Complete list of proteins discussed in the cytoskeleton section.

only present in Tb, Tc

Supplementary Table S9.
Tritryp transporters.

The entire Tritryp predicted gene complement (37,332 CDS) were assessed by similarity searches (BLASTP) against transporter components lodged in the TCDB database (<http://tcdb.ucsd.edu/index.php>). All proteins in the TCDB database have been annotated with an IUBMB approved classification system for membrane transport proteins: the Transporter Classification (TC) system.

Tritryp proteins were classified transitively from the TCDB protein, and hence TC, exhibiting the highest BLASTP similarity. A maximum E-value cut-off of 1e-05 was applied.

TCDB class	Lm	Tb	Tc

Dr Cecilia Alsmark (Cecilia.Alsmark@Newcastle.ac.uk)

Dr T. Martin Embley (Martin.Embley@ncl.ac.uk)

Table S11. List of strongest phylogenetic tree-based cases for prokaryote to eukaryote horizontal gene transfer in the Tritryps.

For the analysis, shorter names were assigned due to software restrictions. Each tree is after one of the Tritryp orthologues within it. The presence of orthologues in the other Tritryp genomes is indicated. Phylogenetic trees for cases of HGT not mentioned in the text can be found in additional supplementary materials as a searchable PDF document (HGTTrees.pdf).

Identifier	Gene name	Product	Tree name	orthologs		
				Lm	Tb	Tc
LM0001	LmjF13.0090	carboxypeptidase, putative	LM0001tctb	x	x	x
